Pollution of our seas and waterways with mercury is a serious environmental problem, but the molecular mechanisms of mercury toxicity remain poorly understood. Because ion channels are trans-membrane proteins having extra-cellular thiol groups that are accessible to environmental mercury, ion channels are a prime target for mercury toxicity. Previous investigators at MDIBL have demonstrated that CFTR, a  $\text{Cl}^-$  channel responsible for salt balance in sharks, is exquisitely sensitive to mercury compared to mammalian CFTR (Sirota et al., *MDIBL Bulletin* 38:105-106, 1999). In this investigation, we examined the sensitivity of  $\text{Ca}^{2+}$ -activated  $\text{Cl}^-$  channels to mercury.  $\text{Ca}^{2+}$ -activated  $\text{Cl}^-$  channels play important roles in epithelial salt and water transport in many cell types (Fuller (ed),  *$\text{Ca}^{2+}$ -activated  $\text{Cl}^-$  Channels*, Academic Press, 2001). We have proposed that  $\text{Ca}^{2+}$ -activated  $\text{Cl}^-$  channels may be encoded by the bestrophin family of proteins (Hartzell et al, *submitted*). This family has 2 highly conserved cysteine residues that face the extra-cellular space that may be susceptible to thiol-reactive reagents such as mercury. In these experiments, we examined the effects of Hg on  $\text{Ca}^{2+}$ -activated  $\text{Cl}^-$  channels in *Xenopus* oocytes. We found that, in contrast to CFTR,  $\text{Ca}^{2+}$ -activated  $\text{Cl}^-$  channels in *Xenopus* oocytes are relatively insensitive to Hg. *Xenopus* oocytes were voltage-clamped with two micro-electrodes and  $\text{Ca}^{2+}$ -activated  $\text{Cl}^-$  currents were elicited by microinjection of 10 nl of 10 mM inositol 1,4,5-trisphosphate ( $\text{IP}_3$ ) into the oocyte as we have previously described (Hartzell, *J. Gen. Physiol.* 108:1-19, 1996). On average,  $\text{IP}_3$  injection elicited  $\text{Ca}^{2+}$ -activated  $\text{Cl}^-$  currents  $\sim 10 \mu\text{A}$  in amplitude at  $+80 \text{ mV}$ . Figure 1 shows that there was no effect of Hg on the  $\text{Ca}^{2+}$ -activated  $\text{Cl}^-$  currents at concentrations between  $10 \mu\text{M}$  (left panel) and  $100 \mu\text{M}$  (right panel). Hg had no significant effect on the background  $\text{Ca}$ -insensitive  $\text{Cl}^-$  currents before  $\text{IP}_3$  injection.

Figure 1. Absence of effect of  $\text{HgCl}_2$  on  $\text{Ca}$ -activated  $\text{Cl}^-$  currents in *Xenopus* oocytes. *Xenopus* oocytes were voltage-clamped with two microelectrodes using an Axon Instruments Gene Clamp 500B amplifier. The bath was grounded via a  $\text{Ag-AgCl}$  electrode

attached to a virtual ground bath clamp (Axon Instruments). The cells were held at a membrane potential of -40 mV and stepped to various potentials between -120 mV and +80 mV for 1-sec. Ca-activated Cl currents were elicited by injection of 10 nl of 10 mM IP<sub>3</sub>. After 10 min, when the Ca-activated Cl currents had reached a maximum amplitude, the peak current at each voltage was plotted. The left panel shows the average current-voltage relationships of 10 oocytes before (open symbols) and during (solid symbols) exposure to 10  $\mu$ M HgCl<sub>2</sub>. The right panel shows the average current-voltage relationships of 8 oocytes before (open symbols) and during (solid symbols) exposure to 10  $\mu$ M HgCl<sub>2</sub>.
